

## An Alternative Proton Source

Dave McGinnis  
April 22, 2005

---

# Motivation

---

- Develop an alternative plan to provide high intensity proton beams for the neutrino program beyond 2010 should budgets and approvals for the planned projects fail to materialize.
- The proposal needs to have the following important features
  - It must be inexpensive (< \$100M or so)
  - It must be completed quickly (before 2012)
  - It should not shutoff the collider complex or the neutrino program for an extended period of time.
- These goals can be accomplished only if:
  - It uses the present Fermilab infrastructure (tunnel enclosures, service buildings, power, utilities, etc.)
  - The project is staged

# Concept

---

- This proposal will only discuss producing 8 GeV protons
  - Acceleration in the Main Injector and MI-RF upgrades are treated in the present Proton Plan
  - Also the present Proton Plan is developing the concept to deal with the vulnerability of RF power tubes in the present Linac

# Concept

---

- The cancellation of the BTeV project eliminates the need to produce antiprotons at Fermilab beyond 2009-2010,
- The present antiproton production complex can be converted into a multi-stage proton accumulator for injection into the Main Injector.
  - Debuncher -> Wide Aperture Booster
  - Accumulator -> Momentum Stacker
  - Recycler -> Box Car Stacker

# Project Staging

---

- Because the concept uses existing infrastructure the performance can be broken into stages
- Project staging has the important benefit of providing
  - a fraction of the total performance
  - at a fraction of the total cost
- The schedule for each stage is driven by physics need and funding availability

# Stages of the Present Proton Plan

---

- Stage 0 - Present Booster -> Main Injector
  - $6.5 \times 10^{16}$  pph
  - 220kW 120 GeV Beam
  - $1.1 \times 10^{16}$  pph BNB
- Stage 1 - Proton Plan Booster -> Main Injector (>2008)
  - $13.6 \times 10^{16}$  pph
  - 370kW 120 GeV Beam
  - $5.1 \times 10^{16}$  pph BNB
- Stage 2 - Proton Plan Booster -> Recycler -> Main Injector
  - $13.6 \times 10^{16}$  pph
  - 725kW 120 GeV Beam

# New Stages for the Multi-Stage Proton Accumulator

---

- Stage 3 - Proton Plan Booster -> Present Booster Aperture Upgrade -> Accumulator -> Recycler -> Main Injector
  - $21.6 \times 10^{16}$  pph
  - 1150kW 120 GeV Beam
- Stage 4 - Proton Plan Booster -> New Booster -> Accumulator -> Recycler -> Main Injector
  - $43.2 \times 10^{16}$  pph
  - 2300kW 120 GeV Beam
  - Option A
    - $56.8 \times 10^{16}$  pph
    - 2300kW 120 GeV Beam
    - $13.6 \times 10^{16}$  pph BNB
  - Option B
    - $64.8 \times 10^{16}$  pph
    - 2300kW 120 GeV Beam
    - $21.6 \times 10^{16}$  pph BNB

## Multi-stage Proton Accumulator Scheme

---

- Stages 0-2 are covered in the present Proton Plan
- The rest of this presentation will discuss Stages 3 and 4

# Multi-stage Proton Accumulator Scheme

---

- Keep the present 400 MeV Linac
- Accelerate in a Wide Aperture Booster
  - Stage 3 - Upgrade the present Booster to run at  $6 \times 10^{13}$  protons/sec
    - Low intensity per pulse -  $4.0 \times 10^{12}$  protons/pulse
    - Fast repetition rate - 15 Hz
  - Stage 4 - New Booster in place of the Debuncher ring to run at  $1.2 \times 10^{14}$  protons/sec
    - High intensity per pulse -  $8 \times 10^{12}$  protons/pulse
    - Fast repetition rate - 15 Hz

# Multi-stage Proton Accumulator Scheme

---

- Momentum stack in the Accumulator
  - Inject in a newly accelerated Booster batch every 67 mS onto the high momentum orbit of the Accumulator
  - Decelerate new batch towards core orbit and merge with existing beam
  - Momentum stack 3-4 Booster batches
  - Extract a single Accumulator batch
    - Every 200 - 270 mS
    - At an intensity of 3-4x a single Booster batch
- Box Car Stack in the Recycler
  - Load in a new Accumulator batch every 200-270mS
  - Place six Accumulator batches sequentially around the Recycler
- Load the Main Injector in a single turn

# Multi-stage Proton Accumulator Production Cycle

# Acceleration in a Wide Aperture Booster

---

- Using the Accumulator as a proton accumulator reduces the peak intensity requirement in the Booster
- Results in a smaller required aperture
  - Smaller space charge tune shift
  - Reduced requirements on acceleration efficiency
- Scaling
  - Use present Booster performance to scale for acceptable beam loss
  - Use PD2 Design report for scaled cost estimate

# Scaling Laws

- Compare designs with the same space charge tune shift

$$\varepsilon_n \propto \frac{N_{inj}}{\beta\gamma^2 \Delta v}$$

- Amount of beam power lost per pulse is inversely proportional to the repetition rate

$$P_L = J_L R$$

- The transverse acceptance is inversely proportional to the amount of beam loss in the “tails” of the beam

$$A_n \propto -\varepsilon_n \ln\left(\frac{N_{inj} - N_{ext}}{2N_{inj}}\right)$$

- The half-aperture of the magnets is proportional to

- The transverse acceptance,
- The momentum acceptance
- The closed orbit displacement

$$\Delta x = \sqrt{\frac{A_n}{\beta\gamma}} \beta_{max} + \frac{\Delta p}{p} D_{max} + \text{c.o.d.}$$

# Present Booster Performance

Summary for Event 10  
From 01-MAR-2005 00:00:00  
to 01-APR-2005 00:00:00

Percentage up time: 88.1  
Total Events: 13605200  
Total Protons: 4.32E+19  
Average Events/second: 5.46  
Average protons/Event: 3.35E+12  
Average protons/hour: 6.58E+16  
Maximum protons/hour: 8.33E+16  
(protons out)/(protons in): .828  
(Joules lost)/(1e12 prot): 23.7

# Wide Aperture Booster - Stage 3

---

- Upgrade the present Booster to run at  $6 \times 10^{13}$  protons/sec
  - Would be 1.1MW at 120 GeV
  - Low intensity per pulse -  $4.0 \times 10^{12}$  protons/pulse
  - Fast repetition rate - 15 Hz
- Acceptable Losses
  - Present
    - $3.35 \times 10^{12}$  protons/pulse
    - 5.46Hz
    - 83% efficiency
    - 70 Joules/pulse lost
  - Stage 3
    - $4.0 \times 10^{12}$  protons/pulse
    - 15Hz
    - 95% efficiency
    - 25 Joules/pulse lost

# Wide Aperture Booster Designs

| Parameter               | Present | Stage 1-2 | Stage 3 | Stage 4 | PD2   |                   |
|-------------------------|---------|-----------|---------|---------|-------|-------------------|
| Extraction Intensity    | 3.4     | 4.7       | 4.0     | 8.0     | 25.0  | $\times 10^{12}$  |
| Rep. Rate               | 5.5     | 8.0       | 15.0    | 15.0    | 15.0  | Hz                |
| Average Beam Power Lost | 443.0   | 443.0     | 443.0   | 443.0   | 443.0 | Watts             |

| D Aperture Height       | 1.9     | 2.0       | 2.0     | 3.0     | 4.2   | in                |

# Stage 1 Wide Aperture Booster Components

---

- Move the notcher from the Booster to the front end of the Linac (< \$100k)
  - Using momentum stacking in the Accumulator eliminates the need for cogging in the Booster
    - Prior to injection into the Accumulator, the injection orbit of the Accumulator is empty
    - The Accumulator injection system can be phase-locked to the Booster which eliminates the need for cogging in the Booster
    - The Booster notch can be made in the Linac
  - Need to upgrade Linac chopper power supply and controls
  - Saves 24 Joules/pulse at  $4.0 \times 10^{12}$  protons/pulse

# Stage 3 Wide Aperture Booster Components

---

- Extraction Septum Upgrades
  - Collimators are presently used to shield small apertures at the extraction septa
  - Remove Long 13 extraction septum (~ \$100k)
    - Place a low intensity dump in the MI-8 line for short batches
    - Use the Long 12 kicker for more extraction kick at Long 3
  - Long 3 Pulsed extraction 3 bump (~ \$1M)
    - Replace 400 MeV doglegs with pulsed 8 GeV 3 Bump
  - Pull collimators out to larger aperture
  - Saves 13 Joules/pulse at  $4.0 \times 10^{12}$  protons/pulse

# Stage 3 Wide Aperture Booster Components

---

- Aperture Upgrade
  - Booster RF Cavity Upgrade (~ \$25M)
    - Build the RF cavities for the new Booster (Stage 2)
      - Install the new cavities in the old Booster
      - Operate the cavities in old Booster until new Booster is ready to be installed and remove and install the new RF cavities in the new Booster
    - Increase the RF cavity aperture by 75% (2.25" → 3")
    - Cavities incorporate
      - Passive HOM dampers
      - Reliable Power electronics
    - Provide 15 Hz capability
  - Proton Plan (Stage 1)
    - Alignment \$0.09M
    - Gamma-t jump \$0.1M
    - Ramped correctors \$2.1M
    - OR-BUMP \$0.7M
      - Also provides 15 Hz capability
    - 30 Hz harmonic \$1.8M
  - Need to save 7 Joules/pulse at  $4.0 \times 10^{12}$  protons/pulse

## Stage 3 Cost Guess (in k\$)

---

|                                       |        |
|---------------------------------------|--------|

| <i>MI Gamma-t jump</i>                | 500    |

---

# Wide Aperture Booster - Stage 4

---

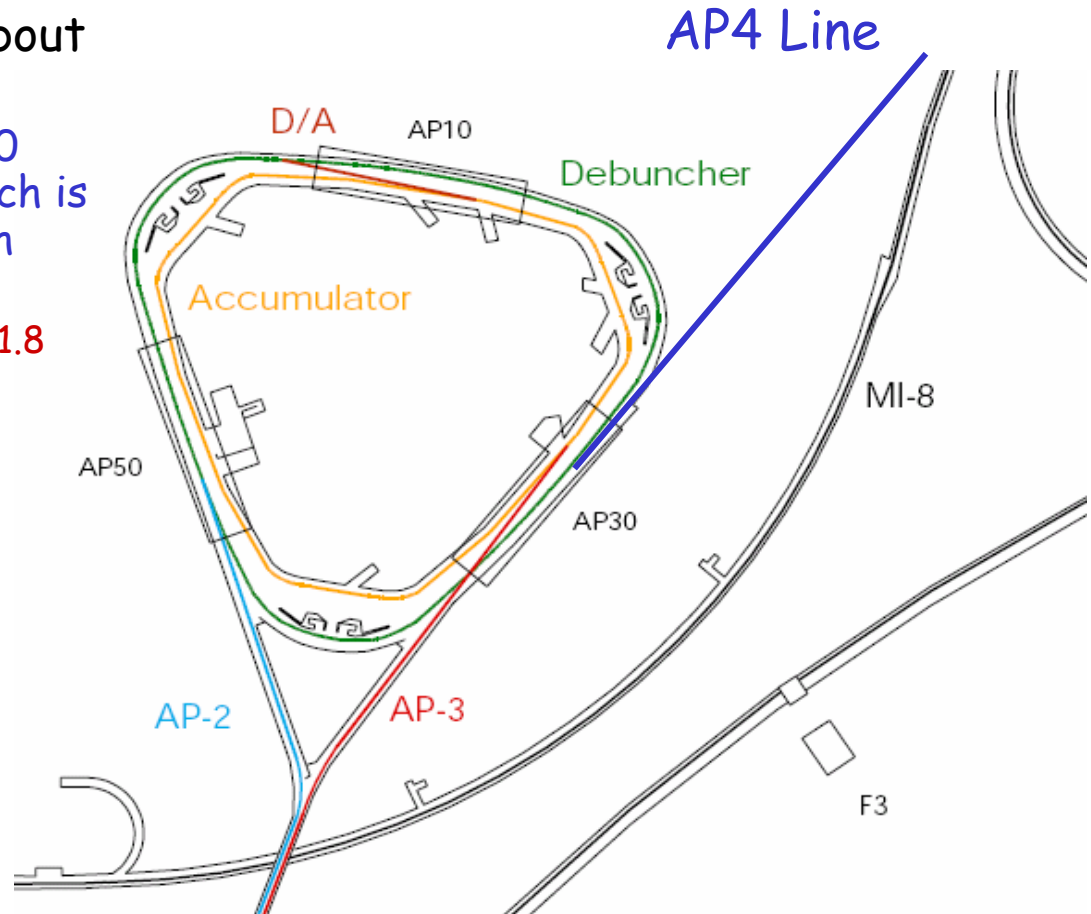

- New Booster in place of the Debuncher ring to run at  $1.2 \times 10^{14}$  protons/sec
  - Would be 2.3MW at 120 GeV
  - High intensity per pulse -  $8.0 \times 10^{12}$  protons/pulse
  - Fast repetition rate - 15 Hz
- Building a new booster in the Debuncher tunnel saves on
  - Tunnel
  - Power & Utilities
  - Service buildings
  - The RF (~25M\$) is purchased in Stage 3

# Acceleration in a Wide Aperture Booster

| Parameter               | Present | Stage 1-2 | Stage 3 | Stage 4 | PD2   |                   |
|-------------------------|---------|-----------|---------|---------|-------|-------------------|
| Extraction Intensity    | 3.4     | 4.7       | 4.0     | 8.0     | 25.0  | $\times 10^{12}$  |
| Rep. Rate               | 5.5     | 8.0       | 15.0    | 15.0    | 15.0  | Hz                |

| D Aperture Height       | 1.9     | 2.0       | 2.0     | 3.0     | 4.2   | in                |

# AP-4 Line

- The old Booster is connected to the new Booster via a re-built AP4 Line
- The new AP4 line is about 240 meters in length
  - Compared to the 600 MeV line of PD2 which is 250 meters in length
    - Magnets 1 M\$
    - Civil Construction 1.8 M\$

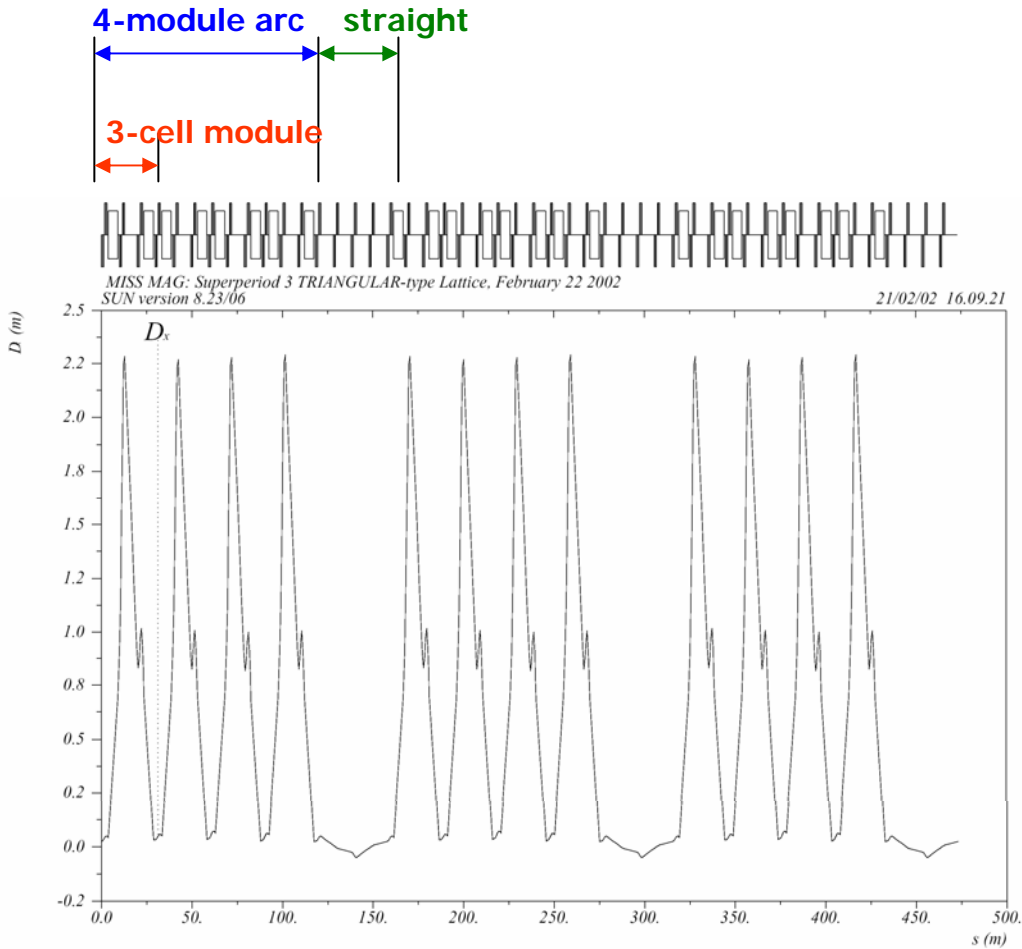

# Features of the New Booster

---

- Ramps from 400 MeV to 8 GeV
- Fast cycling (15 Hz)
- Large aperture
- Separated function magnets.
- Dual harmonic power system for an asymmetric acceleration ramp
- Does not go through transition
- Zero dispersion at the RF cavities
- Modern RF cavity design with higher order mode dampers.
  - Install the new cavities in the old Booster during Stage 3
  - Operate the cavities in old Booster until new Booster is ready to be installed and remove and install the new RF cavities in the new Booster

# Stage 4 Triangular Lattice

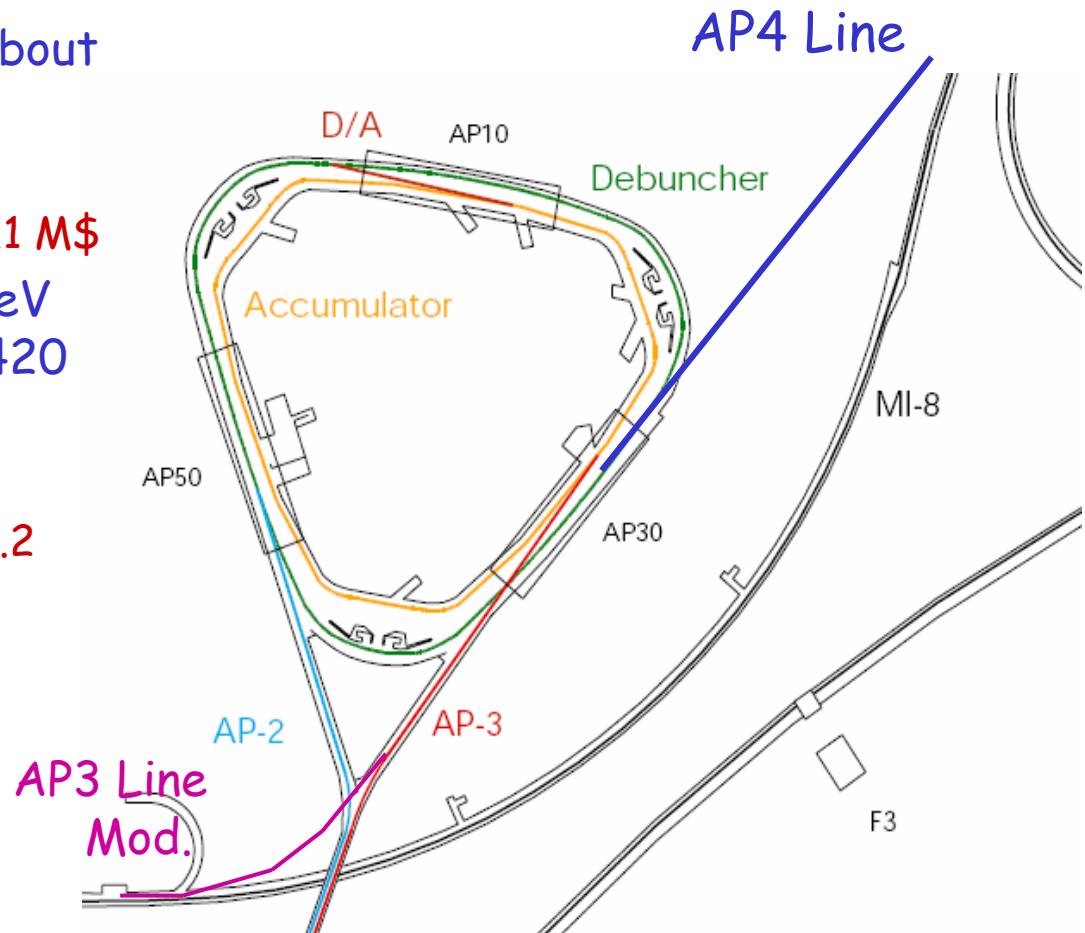

## Stage 4 Triangular Lattice

---

- Triangular shape to fit to the Debuncher footprint
- No transition crossing ( $\gamma_t = 18.1$ )
- Zero dispersion straights
- Simple: 1 type of dipole, 1 type of quad (QF and QD same length)
- Doublet lattice,  $90^\circ$  phase advance per cell
- 3 cells per module, with missing dipole in the mid-cell,  $270^\circ$  phase advance per module
- 4 modules per arc,  $6\pi$  phase advance per arc
- No need for dispersion suppressor
- Plenty of free space: 24 x 7 m
- Low beta-function (15 m) and dispersion (2.3 m)
- Good optical properties (large dynamic aperture, weak dependence of lattice functions on amplitude and  $dp/p$ )

# AP-3 Line Modification

- The AP3 line needs to be connected to the MI-8 line
  - The modification is about 100 meters in length
    - Magnets 0.8 M\$
    - Civil Construction 1.1 M\$
  - Compared to the 8 GeV line of PD2 which is 420 meters in length
    - Magnets 1.9 M\$
    - Civil Construction 2.2 M\$

# Cost Comparison Between Stage 4 and PD2

---

- Reuse the pbar tunnel
  - Saving \$43M in civil
  - However include \$3M for radiation shielding
- Reduce magnet aperture from 4" x 6" to 3" x 5"
  - Saving \$20M in magnet and power supply cost.
- Use new type of beam pipe
  - Saving \$1M in vacuum
- Reuse utilities
  - Existing in Pbar Tunnel
  - Lower beam power.
  - saving \$4.4M
- Reuse controls
  - saving \$2M
- Do not need foil changer,
  - saving \$0.15M.
- The new cost estimate is about \$50M,
  - The RF (~25M\$) is purchased in Stage 3

## Stage 4 Cost Guess (in k\$)

---

|                                 |        |
|---------------------------------|--------|
| Stage 4                         | 50,200 |
| <i>Magnets</i>                  | 17,000 |

# Stage 4 Booster vs BNL AGS Booster

|                      | Stage 4              | AGS Booster         |
|----------------------|----------------------|---------------------|
| Circumference (m)    | 505                  | 201                 |
| Injection (MeV)      | 400                  | 200                 |
| Extraction (GeV)     | 8                    | 1.5                 |
| Rep rate (Hz)        | 15                   | 7.5                 |
| Total dipoles        | 24 × 5.2 m = 124.8 m | 36 × 2.4 m = 86.4 m |
| Total quads          | 96 × 1.24 m = 119 m  | 48 × 0.5 m = 24 m   |
| Beam pipe aperture   | 3 in × 5 in          | 2.8 in × 5.9 in     |
| Max β function (m)   | 14.8 / 15.2          | 13.9 / 13.7         |
| Max dispersion (m)   | 2.3                  | 2.9                 |
| Transition γ         | 18.1                 | 4.79                |
| Beam intensity       | $7 \times 10^{12}$   | $2 \times 10^{13}$  |
| Year constructed     | TBD                  | 1991                |
| Construction cost    | \$75M (estimated)    | \$32M (1991)        |
| Civil cost included? | No                   | Yes                 |

- Adjust \$32M in 1991 for 14 years of 4% of inflation = \$55M
- Scale the cost as the length in magnets = \$122M
- Remove civil construction = \$122M - \$43M = \$79M

# Momentum Stacking in the Accumulator

---

- After acceleration in the Booster the beam will be transferred to the Accumulator ring.
- Using the Accumulator as a proton accumulator reduces the peak intensity requirement in the Booster
- Results in a smaller required aperture for the Booster
  - Smaller space charge tune shift
  - Reduced requirements on acceleration efficiency
- The Accumulator was designed for momentum stacking
  - Large momentum aperture  $\sim 84 \times 2.8$  eV-Sec
  - Injection kickers are located in 9m of dispersion
  - Injection kickers do not affect core beam

# Advantages of Momentum Stacking

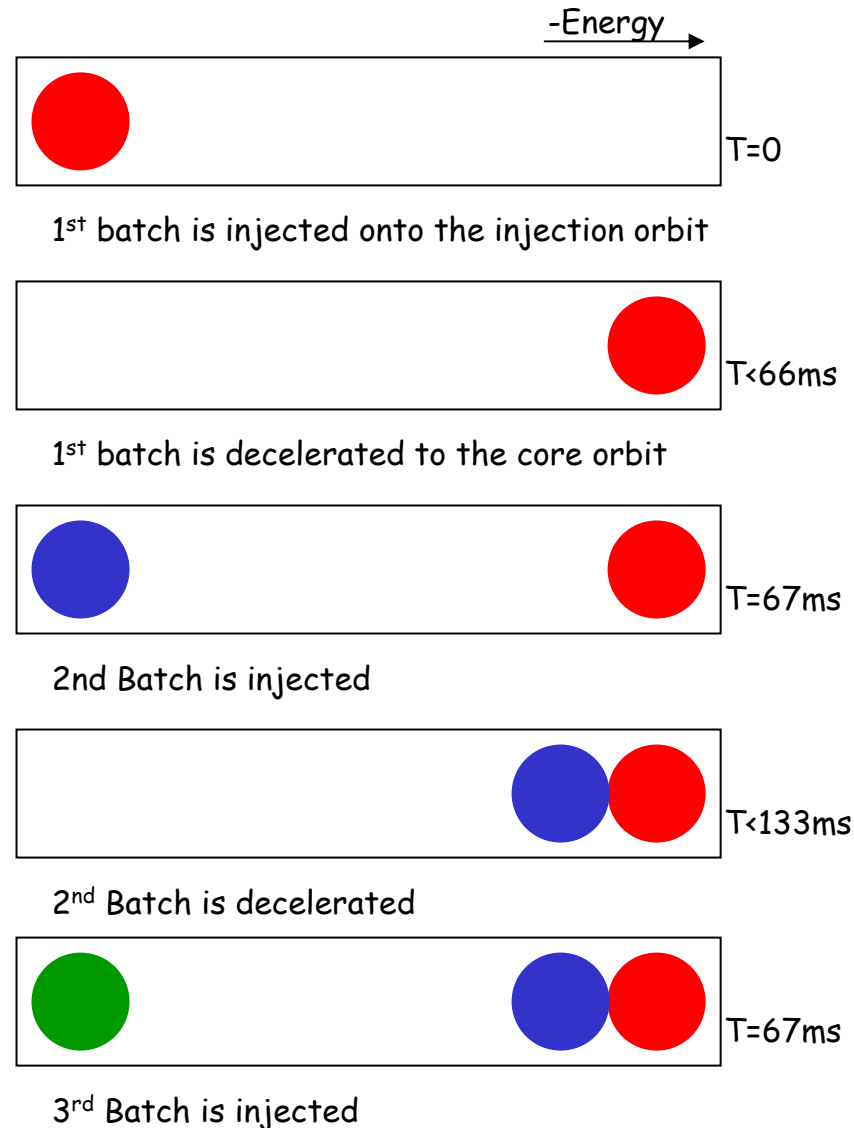

---

- Transient Beam Loading
  - Slip stacking or barrier bucket stacking requires manipulating intense beams with low RF voltages in a mostly empty circumference
  - In momentum stacking, the circumference is always uniformly loaded
- Speed of process
  - Injected beam can be decelerated quickly towards the core beam
- Longitudinal emittance dilution
  - The core beam can be debunched during stacking process reducing the amount of "white spaces"
- Cogging in the Booster
  - Prior to injection into the Accumulator, the injection orbit of the Accumulator is empty
  - The Accumulator injection system can be phase-locked to the Booster which eliminates the need for cogging in the Booster
  - The Booster notch can be made in the Linac

# Mechanics of Momentum Stacking

- Inject in a newly accelerated Booster batch every 67 mS onto the high momentum orbit of the Accumulator
- The freshly injected batch is decelerated towards the core orbit where it is merged and debunched into the core orbit
- Momentum stack 3-4 Booster batches
  - The longitudinal emittance of a batch at 8 GeV from the present Booster is  $84 \times 0.1 \text{ eV-sec}$
  - The present momentum aperture of the Main Injector is  $0.5 \text{ eV-Sec}$  for a 53 MHz bunch
  - Will need at  $\gamma_+$  jump system in the Main Injector ( $\sim \$0.5\text{M}$ )

# Extraction From the Accumulator

---

- After 3-4 batches have been stacked begin preparing to extract all the beam from the Accumulator to the Recycler
- Re-bunch the entire stacked beam at  $h=4$  in the Accumulator (2.5 MHz)
  - 2.5 MHz would provide a large gap between buckets which could accommodate kicker rise time
  - Could consider higher harmonic bunching ( $h=21$ , RF frequency = 13.2MHz)
    - Keep the momentum spread low
    - Keep synchrotron frequency high
- Other Schemes
  - Re-bunching at 53 MHz would require a gap placed in the beam for kicker rise time
    - Speed and voltage of a barrier bucket is a concern
  - Preserve gap from injection by never debunching the Booster batches and slip stacking the gaps
    - Revolution frequencies are close so slipping would be slow
    - Emittance dilution is a concern

# Extraction From the Accumulator

---

- Accelerate the beam to the extraction orbit
  - Phase lock to the Recycler
    - If the accumulator is at  $\eta=0.023$ , the revolution frequency of the Recycler is harmonically related to the revolution frequency of the extraction orbit of the Accumulator
  - Kick the beam into the AP3 line using the Accumulator high dispersion extraction kickers
    - Might have to extend the momentum range of the extraction kicker
      - Place an extra kicker where the present 4-8 GHz momentum cooling system is presently located

# Box Car Stacking in the Recycler

---

- After 3-4 booster batches have been momentum stacked in the Accumulator, the beam would be transferred to the Recycler.
  - 2.5 MHz synchronous transfer
  - Accumulator phase locked to the Recycler
- The Accumulator is  $1/7$  of the Recycler's circumference
- Boxcar stack six of the Accumulator batches (which contain 3-4 of the Booster batches), leaving  $1/7$  of the Recycler ring for an abort gap.
- After 6 Accumulator batches have been stacked into the Recycler do a 2.5 MHz synchronous transfer to the Main Injector
- In the Main Injector
  - perform a 2.5 MHz bunch rotation to reduce the momentum spread
  - Re-capture in 53 MHz buckets for acceleration.

## Booster Neutrino Beamline (BNB) Option

---

- After Stage 4 is complete, the old Booster is abandoned
- The present Linac can support pulse lengths in excess of  $50 \mu\text{s}$ 
  - A 40mA Linac beam pulse for  $50 \mu\text{s}$  has  $12.4 \times 10^{12}$  particles
- From a single Linac pulse, a chopper placed in the 400 MeV line would be able to send
  - $8.2 \times 10^{12}$  protons to the new booster
  - $4.2 \times 10^{12}$  protons to the old booster.
- This would require an RF acceleration system in both Boosters.

# Booster Neutrino Beamline (BNB) Option Option

---

- An RF acceleration system in both Boosters.
  - Option A:
    - Move the RF system built for Stage 3 into the new booster
    - Re-install the old RF system into old Booster
    - Comments
      - Inexpensive
      - Keeps BNB at  $13.6 \times 10^{16}$  protons/hour
  - Option B:
    - Keep the RF system built for Stage 3 in the old Booster
    - Build a new set of cavities for the new Booster.
    - Comments
      - Expensive ~ \$25M
      - Gets BNB to  $21.6 \times 10^{16}$  protons/hour
      - Keeping the old Booster running while installing the new Booster makes the transition between Stage 3 to Stage 4 easier

# Summary

---

- The present antiproton production complex can be converted into a multi-stage proton accumulator
  - That supplies enough protons for a 1.1 MW 120 GeV beam for a cost of about \$40M (\$5M of which is already funded in the present Proton Plan)
  - That can be upgraded to provide enough protons for a 2.3 MW 120 GeV beam for an additional cost of about \$50M
- Because the concept uses existing infrastructure the performance can be broken into stages
  - Project staging has the important benefit of providing
    - a fraction of the total performance
    - at a fraction of the total cost
  - The schedule for each stage is driven by physics need and funding availability
- Integrating the present Booster into this scheme could in addition provide 8 GeV protons in 1.6  $\mu$ S bursts at a rate of 14-21 $\times$ 10<sup>16</sup> protons/hour for a Booster Neutrino Beam (BNB)

## Things To Do

---

- Get cost estimate for Booster RF upgrade
- Lattice design for the new Booster
- Layout of AP3 modification and AP4 line
- Simulate momentum stacking
- Simulate extraction from the Accumulator
